

Standard Test Methods for Evaluating Coatings For High Temperature Service¹

This standard is issued under the fixed designation D 2485; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 These test methods cover the evaluation of the heat-resistant properties of coatings designed to protect steel surfaces exposed to elevated temperatures during their service life. Two test methods are described as follows:

Method A—Interior Service Coatings

Method B—Exterior Service Coatings

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 *This standard does not purport to address the safety concerns, if any, associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Specific hazard statements are given in Section 5.

3. Summary of Test Methods

3.1 Panels suitably coated with the material under test are evaluated under one or both of two test methods depending on the intended usage.

3.1.1 *Test Method A, Interior Service Coatings*—Coated panels are heated for 24 h in a muffle furnace at a temperature agreed upon between the purchaser and the seller. One panel is plunged into water and the other cooled and then subjected to a bend test.

3.1.2 *Test Method B, Exterior Service Coatings*—Coated panels are subjected to temperatures that increase in steps from 205 to 425°C (400 to 800°F). One panel is subjected to salt spray for 24 h, and one is exposed outdoors for 12 months.

3.2 When tests are completed, the panels are examined for evidence of film degradation including rust formation, blistering, loss of adhesion, dulling, and chalking.

4. Significance and Use

4.1 Some coating systems are developed for use over steel that is exposed to high temperatures during service life. This method provides an accelerated means of determining the performance of these coating systems. Testing of coatings designed for interior service, and of coatings designed for exterior (weather-exposed) service is included.

5. Apparatus

5.1 Automatic spray equipment as described in Practices D 823 (Method A) or any other suitable method that will give the required uniformity of film and film thickness.

5.2 Muffle furnace capable of maintaining the temperatures described in 7.2 and 7.3.

5.2.1 **Warning:** Due to the high temperatures involved in operating the muffle furnace, extreme caution should be used.

5.3 Salt spray apparatus as described in Practice B 117.

6. Panel Preparation

6.1 *Type*—Panel dimensions shall be established by prior agreement between the purchaser and the seller. Use panels of 6.4 mm (1/4 in.) hot-rolled steel conforming to Specification A 36/A 36M or Specification A 283/A 283M, or when appropriate, Specification A 285/A 285M for the water quench test

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings, Materials, and Applications and are the direct responsibility of Subcommittee D01.27 on Accelerated Testing.

Current edition approved May 15, 1991. Published July 1991. Originally published as D 2485 – 66 T. Last previous edition D 2485 – 84.

⁶ *Annual Book of ASTM Standards*, Vol 14.02.

in Test Method A, and for all tests under Test Method B. For the bend test in Test Method A, the panels must be thin and soft enough to be bent as described in Test Methods D 522.

6.2 Cleaning—Clean the panels for both test methods in accordance with Practice D 609, Methods B or D. Then, using a fine silica sand (graded to pass through a No. 40 (425- μ m) sieve), blast the panels for Method B to “white” metal (removing all mill scale and rust) so that the panels comply with grade A SP-5 of Standard D 2200. Other blast media and blast methods are acceptable if agreed upon between the buyer and the seller. Blast-cleaned panels cannot be subjected to the bend test because they are too thick to bend.

6.3 Coatings Applications—Apply the coatings by automatic spray, Method A of Practices D 823, or by any other suitable method that will assure the required uniformity of film thickness. The number of coats, technique, and cycle for drying between coats of multicoat systems, limits of dry film thickness, and drying time before exposure shall be established by prior agreement between the purchaser and the seller. Determine dry film thickness in accordance with Test Methods D 1186. Allow coatings that air dry at ambient temperature to dry a 168 h at a temperature of $24 \pm 2.5^\circ\text{C}$ ($75 \pm 5^\circ\text{F}$) prior to exposing to test conditions. Bake coatings that require heat conversion in accordance with the recommendation of the supplier.

7. Procedure

7.1 Sampling—When panels have been coated at another location, select at random from different packages two specimens for each method of each type of coating under investigation.

7.2 Test Method A:

7.2.1 Place **one panel** each of the two types described in 6.1 and 6.2 coated with each paint under test in a muffle furnace maintained at the test temperature mutually agreed upon between the purchaser and the seller, and allow to remain for 24 h. At the end of this time plunge one of the panels immediately into water maintained at $70 \pm 5^\circ\text{F}$ ($21 \pm 2.5^\circ\text{C}$). After removing from the water, examine the coating film for evidence of film failure including dulling, blistering, cracking, and loss of adhesion. Allow the second panel to cool at a room temperature of $24 \pm 2.5^\circ\text{C}$ ($75 \pm 5^\circ\text{F}$) for 1 h, then rapidly bend double over a 12.7-mm ($\frac{1}{2}$ -in.) diameter steel mandrel with coated side uppermost in accordance with Test Methods D 522, Method B. Examine this panel for evidence of film degradation such as cracking and loss of adhesion.

7.3 Test Method B:

7.3.1 Expose duplicate coated panels finished with the materials under test to the elevated temperature test schedule mutually agreed upon between the purchaser and the seller. In the absence of such a specified schedule use the following:

7.3.2 Place the panels in a muffle furnace maintained at 205°C (400°F) for 8 h, then increase the temperature to 260°C (500°F) for 16 h. Increase the temperature in 55°C (100°F) increments, alternating the time periods indicated, to the final temperature maximum previously agreed to between the purchaser and the seller. Thus the schedule would be:

205°C (400°F) for 8 h

260°C (500°F) for 16 h

315°C (600°F) for 8 h

370°C (700°F) for 16 h

425°C (800°F) for 8 h

NOTE 1—Many high temperature paints depend upon service conditions to provide the extreme heat required to cure or sinter their films. If these paints are never exposed to the extreme heat, they may be found to be unsuitable. Consequently, it is good practice to make observations also at temperatures less than the expected service temperatures.

7.3.3 Remove the test panels and make a visual inspection following exposure at each temperature level for evidence of failure, including peeling, cracking, blistering, abnormal discoloration, or loss of adhesion, using ASTM standards where possible. Disregard such failures up to 6.4 mm ($\frac{1}{4}$ in.) in from the edges of the test panels.

7.3.4 At the end of the complete exposure, remove the panels from the oven or muffle furnace and allow to air cool at ambient temperature for a minimum period of 1 h. As described in 7.3.3, inspect for evidence of failure due to the high temperature exposure.

7.3.5 If both panels of each pair pass the heat test satisfactorily, use them, respectively, for salt spray (fog) testing and exterior exposure testing.

7.3.5.1 Place one panel of each pair in a salt spray cabinet operated in accordance with the requirements of Practice B 117, for a period of 24 h. At the conclusion of the exposure period, examine each panel for rusting or any other evidence of corrosive attack.

7.3.5.2 Expose the second panel of each pair on an insulated-type rack, as described in Practice G 7, or as agreed upon between the purchaser and seller, for a period of 12 months. Make a visual inspection after 6 months and after termination of the exposure. The site to conduct the test and the angle of the exposure rack should be agreed upon between the purchaser and the seller, and should relate to the end-use application of the coating.

8. Report

8.1 Report the following information:

8.1.1 Description of substrates, substrate preparation, and application conditions used.

8.1.2 Air drying and the baking schedule used.

8.1.3 Details of outdoor exposure when applicable, including:

8.1.3.1 Exposure site, type (insulated rack, black box, open rack, etc.) and angle of exposure,

8.1.3.2 Date of exposure start,

8.1.3.3 Radiation data in terms of kilojoule per square metre or langleys during exposure period, and

8.1.4 Any defects or changes as described under Section 7.

9. Precision

9.1 Four operators in four laboratories tested six materials covering a range of heat-resistant properties, and were able to rank products in order of their heat-resisting qualities. Since rankings were of a qualitative nature, no mathematical statement of reproducibility was established.

10. Keywords

10.1 heating tests; paints; resistance; heat; temperature tests;
elevated

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.
